Title

Method and device in connection with pressure measurement

Field of the invention

- 5 The present invention relates to a method and a device according to the preambles of the independent claims.

Background of the invention

- 10 A biventricular pacing system includes pacing electrodes arranged at least in both the left and right ventricles of the heart. This type of systems also often includes an atrial electrode arranged in the right atrium.

- 15 The present invention is applicable both during procedures of implanting electrode leads connected to medical implants, e.g. pacemakers, defibrillators or cardioverters, and at later follow-up procedures for evaluating the positions of the electrodes in the heart. In order to achieve a desired effect of a stimulation pulse it is of great importance that the electrode surface has good contact with the heart tissue so that the tissue may be stimulated by using stimulation pulses having as low stimulation energy as possible.

- 20 In biventricular systems the timing or synchronization between stimulation pulses applied to the right and left ventricle is very important in order to adapt the stimulation as much as possible to the heart's intrinsic rhythm. The synchronization is related to the cardiac output and a general object for pacemakers is to achieve as high cardiac output as possible.

- 25 In US-6,238,420 is known a four-chamber pacing system for optimizing cardiac output and determining heart conditions. The system utilizes impedance sensing for determining optimum pacing parameters, e.g., for pacing the left ventricle so that left heart output is maximized. Impedance sensing in the left heart also provides timing of mechanical contraction, and the pacemaker controls pacing to maintain bi-ventricular mechanical synchronization adjusted for maximum cardiac output.

- 35 In connection with implantable heart stimulators it has been found very advantageous to measure the pressure in the left ventricle of the heart in order

to obtain information related to the function of the heart stimulator and especially if the desired therapy is achieved by the stimulating pulses.

5 A pressure sensor assembly mounted on a guide wire and applicable for measuring intravascular pressure, and in particular intracardiac pressure, is disclosed in US-5,226,423. The pressure sensor assembly is in particular applicable for insertion into the left ventricle of the heart via coronary sinus, according to well-established implantation techniques.

10 In the published US patent application 2002/0072880 is disclosed a system that includes an interactive graphical user interface for controlling the performance of, and for displaying on a screen, measured values and calculated results based on the measured values obtained by a guidewire-mounted pressure sensor, e.g. of the kind disclosed in the above-mentioned US-5,226,423..

15 The overall object with the present invention is to simplify for the physician, during the clinical procedure of implantation or follow-up, to use information obtained by pressure measurements in the left ventricle to optimize predetermined medical implant settings in a medical implant controlling the
20 application of stimulation pulses to the left and right ventricles of the heart.

Summary of the invention

The above-mentioned object is achieved by the present invention according to the independent claims.

25 Preferred embodiments are set forth in the dependent claims.

Thus, for each stimulation setting the pressure value in the left ventricle is continuously measured and displayed at a display means. The first derivative of the measured pressure value is simultaneously determined and also displayed at
30 the display means.

The average or median value of the maximum values of the first derivative pressure curve is determined for a preset measurement period.

This is repeated for a number of different stimulation settings and the average/median value for each setting is displayed together with identification data. The identification data includes the stimulation setting (being the AV and VV intervals). By using this information presented on an measurement session
5 list the physician may easily identify the optimal setting, being the setting where the average value is maximal. Alternatively, the information may be presented directly in a two-, or three-dimensional graph.

The pressure is measured by using a miniaturised pressure sensor arranged at
10 the distal end of a pressure sensing guidewire inserted into the left ventricle according to well-established technique. The measured pressure and the calculated first derivate of the pressure is displayed in real-time on a display means and the average value of the maximum derivative is determined. A
15 number of measurements are performed for different $V_{right}-V_{left}$ values where V_{right} is the time when stimulating in the right ventricle and V_{left} is the time when stimulating in the left ventricle. Thus, the time difference Δ is preferably in the range of -100 - 100 ms. The time difference is determined where the average value of the maximum derivative is maximal.

Also the AV interval, being the time between atrial and ventricular stimulation in
20 the right side of the heart, may be varied (preferably between 30 and 120 ms) in order to obtain an optimal setting for the pacemaker.

Further calculations may be performed, e.g. second time derivative values of the pressure curve may be determined and used in the process.

25 Short description of the appended drawings

Figure 1 shows a flowchart of the method according to the present invention.
Figure 2 is a block diagram including a pressure measurement device according to the present invention.

Figure 3 is a block diagram including a pressure measurement device of a
30 preferred embodiment according to the present invention.

Figure 4 shows an image of a first screen display illustrating the present invention.

Figure 5 shows an image of a second screen display illustrating the present invention.

Detailed description of preferred embodiments of the invention

The present invention will now be described with references to the accompanying figures.

5

In figure 1 a flowchart is illustrated of the method according to the invention.

A measurement session is initiated by determining an appropriate initial implant setting for the medical implant to be tested. The setting to be tested is inputted at a "View" display screen (see below in connection with the description of figure 5) and the medical implant (ref. sign 20 in figure 2) is programmed with that setting by the medical implant programmer (22 in figure 2) in accordance with well-known techniques. After that the measurement period may start. (step 100).

15 The implant setting includes a first time difference $\Delta 1$ being the time between stimulations in the left and right ventricles. If also an atrial electrode lead is implanted (see figure 3) the implant setting further includes a second time difference $\Delta 2$ being the time between stimulations in the right atrium and right ventricle.

20

In one straight-forward use of the present invention the implant setting is varied by the physician that manually inputs different values at the display screen and then manually programs the medical implant with that value(s). An obvious alternative would be to perform this "value search" automatically. This could be done either under control from the medical implant programmer or under control from the pressure measurement device. In both cases the implant device setting is varied according to a predefined search pattern where all possible, or a predetermined subset of all possible, combinations of AV- and VV-intervals are checked with regard to the measured pressure and calculated dP/dt .

25
30

The inventive method for monitoring, determining by measurement and calculation and graphically displaying physiological variables related to blood pressure, comprises at least the following steps:

a) detecting continuously during a measurement period left ventricular

- pressure of a heart (P_{LV}), derived from a guidewire-mounted pressure sensor;
- b) transducing said pressure to a processable signal and delivering said processable signal to a processing means being able to process said processable signal;
- 5 c) receiving said processable signal;
- d) calculating the first time derivative (dP_{LV}/dt) of said left ventricular pressure by processing said signal;
- e) forming curves and displaying said curves of data representing the pressure (P_{LV}) and the first time derivative of said pressure (dP_{LV}/dt).
- 10 All these steps a)-e) are covered by step 102 in figure 1.

The method is continued by step 104:

- f) calculating the value of a predefined parameter of said first time derivative curve during the measurement period, and step 106:
- 15 g) displaying said calculated value in a measurement session list that may include calculated values from other measurement periods.

The measurement session list will be further discussed below in relation to figure 5.

- 20 The predefined parameter is the average value, or alternatively the median value, of the peak values of the first derivative curve during a measurement period. In situations where artefacts and disturbances are to be suppressed only part(s) of the first time derivative curve that fulfil certain calculation criteria are included when calculating the value of the predefined parameter. This criteria
- 25 may include certain max and min limits for the peak values in order to include them in the average/median value calculation.

- As initially stated the pressure measurement is performed during a measurement period using predetermined medical implant settings in a medical
- 30 implant controlling the application of stimulation pulses at least to the left and right ventricles of the heart.

When the measurements are performed for all different settings the method according to a preferred embodiment further comprises the step of choosing the implant setting from the list that fulfils an optimal implant setting criterion. The

optimal implant setting criterion is to choose the implant setting having the maximum amplitude of the average, or median, values in the list.

5 The abovementioned measurement period is less than 30 seconds and preferably about 10 seconds.

A measurement session list may include calculated values from measurement periods obtained during a measurement session of less than 60 minutes and preferably less than 30 minutes.

10 The present invention also relates to a computer program product directly loadable into the data storage (ref. sign 16 in fig. 3) of the processing means within a control unit arranged in the pressure measurement device. The computer program product comprises the software code means for performing the steps of any of the appended method claims.

15 The invention further comprises a computer program product that can be stored on a computer usable medium, comprising readable program for causing a processing means in a control unit to control an execution of the steps of any of the appended method claims.

20 With references to figures 2 and 3 showing block diagrams of the present invention the pressure measurement device now will be further described. The pressure measurement device 2 includes a pressure measurement guidewire 4 provided with a pressure sensor 6 adapted to perform pressure measurements in the left ventricle of a heart 8. The wire is connected to a measurement unit 10
25 to receive pressure measurement values obtained from the sensor, and to a processing means 12 for determining a real-time curve of the obtained pressure values and the measurement device also includes a display means 14 for displaying the curve during a measurement period.

30 The processing means determines a real-time curve of first derivative values determined from the pressure curve and the display means 14 displays the determined first derivative curve, and the processing means also calculates and displays a value of a predefined parameter of the first derivative curve during said measurement period.

The pressure measurement device is adapted to implement the method described above in accordance with all details given in the description of the method.

5 The bi-directed arrow between the pressure measurement device 2 and the medical implant programmer 22 indicates the communication between these units. This could be either by manual programming of the programmer by the physician or automatically if an automatic value search is performed. The arrow between the medical implant and the programmer 22 indicates normal bi-directed telemetry communication.

10

In figure 3 a block diagram illustrates a preferred embodiment where further details of the measurement device 2 are illustrated. Herein the pacemaker 20 is provided with an atrial electrode lead in addition to the leads shown in figure 2. The arrows indicate one typical procedure when implementing the inventive method: the implant setting is inputted at the display screen of the display means 14; these setting are then communicated by the pacemaker control unit 22 to the pacemaker 20 that applies the setting. The pressure sensor measures the pressure during a measurement period in accordance with the method as previously described.

20

Figure 4 shows an image of a first screen display illustrating the present invention.

The pressure measurement device includes a display means being an interface for controlling the pressure measurements and for displaying curves and values. In figure 4 a first screen display is shown, being the "Live" display, which shows the curves of the pressure and the calculated derivative during the measurements. The vertical axes designate the pressure in mmHg and dP/dt in mmHg/s, respectively. The horizontal axes cover a measurement period of approximately 7 seconds. The measurement is initiated by pressing the measure button in the middle at the bottom of the screen and terminated by pressing a stop button (not shown). The figures to the right on the screen show the maximum and the minimum values of the derivative of the measurement period.

25

30

When the measurement is performed the "View" button may be pressed and then the screen display as shown in figure 5 becomes visible.

The upper curve shows the pressure curve for the obtained pressure during the measurement period and the lower curve shows the first derivative curve of the pressure curve. These curves have the same designations of the axes as the curves in figure 4.

In the upper curve a vertical cursor line can be seen at approximately 3,10 seconds. This line may be moved by some kind of pointer means, e.g. a mouse, and in the upper right part of the display screen the pressure value at the location of the cursor line is indicated, in this case 10 mmHg.

In the lower curve, showing the derivative curve, the extreme points are indicated by white markings. A dashed cursor line can be seen at approximately 3,20 seconds and the dP/dt value is shown to the right, in this case 2.

Above this, the calculated average values for the maximum and minimum dP/dt are shown, in this case (2279)/(-1929).

Below that is shown the maximum and minimum values for the heart cycle where the cursor is located, in this case 2226/-1902.

The measurement session list is shown as a table at the bottom of the screen display. The table includes inter alia patient identity, date, time, type of electrodes (RA, RV, CS), state (here biventricular stimulation), AV-interval and VV-interval, Rate, calculated dP/Dt and also a comment field.

Above the table is shown a bar where values for some of these parameters may be inputted. These parameters are primarily related to the settings of the medical implant. In the bar from left to right: RA lead (right atrial lead) in position CSO (coronary sinus ostium); RV lead (right ventricular lead) in position RVO (right ventricular outflow); CS lead (coronary sinus lead) in position (superior-inferior position) Apex (apical position); STATE BiV (biventricular pacing); Pace/Sens (indicates if in pacing or sensing mode); AV(ms) - the value of the AV-interval presently used by the pacemaker; VV(ms) - the value of the VV-interval presently used by the pacemaker; Rate (bpm) - presently used stimulation rate.

It should be noted that it is not necessary to use all fields, e.g. if no atrial electrode is used there is no AV-interval available.

5 In a third display screen (not shown), which is available when pressing the "Result"-button, the table is graphically displayed. This may be in a two-dimensional curve having VV-values along the x-axis and dP/dt along the y-axis where the peak value of that curve indicates an optimal setting for the medical implant.

In an alternative display screen also the AV-values are used and plotted along the z-axis. The display screen then shows a three-dimensional illustration of the calculated result. The optimal setting may then be found where the 3D-curve has its maximum.

10

The present invention is not limited to the above-described preferred embodiments. Various alternatives, modifications and equivalents may be used. Therefore, the above embodiments should not be taken as limiting the scope of the invention, which is defined by the appending claims.

Claims

1. Method for monitoring, determining by measurement and calculation and graphically displaying physiological variables related to blood pressure, comprising at least following steps:
 - a) detecting continuously during a measurement period left ventricular pressure of a heart (P_{LV}), derived from a guidewire-mounted pressure sensor;
 - b) transducing said pressure to a processable signal and delivering said processable signal to a processing means being able to process said processable signal;
 - c) receiving said processable signal;
 - d) calculating the first time derivative (dP_{LV}/dt) of said left ventricular pressure by processing said signal;
 - e) forming curves and displaying said curves of data representing the pressure (P_{LV}) and the first time derivative of said pressure (dP_{LV}/dt);
 - f) calculating the value of a predefined parameter of said first time derivative curve during the measurement period, and
 - g) displaying said calculated value in a measurement session list that may include calculated values from other measurement periods.
2. Method according to claim 1, characterized in that said predefined parameter is the average value for the peak values of the first derivative curve during a measurement period.
3. Method according to claim 1, characterized in that said predefined parameter is the median value for the peak values of the first derivative curve during a measurement period.
4. Method according to any of claims 1-3, characterized in that in step f) only parts of the first time derivative curve that fulfil certain calculation criteria are included in calculating the value of the predefined parameter, wherein this results in that artefacts and disturbances are suppressed.

5. Method according to claim 1, characterized in that the pressure measurements are performed during a measurement period using predetermined medical implant settings in a medical implant controlling the application of stimulation pulses to the left and right ventricles of the heart,
- 5
6. Method according to claim 5, characterized in that the method further comprises the step of choosing the implant setting from the list that fulfils an optimal implant setting criterion.
- 10 7. Method according to claim 6, characterized in that said optimal implant setting criterion is to choose the maximum amplitude of the average values.
- 15 8. Method according to claim 5, characterized in that the implant setting includes a first time difference $\Delta 1$ being the time between stimulations in the left and right ventricles.
9. Method according to claim 8, characterized in that the implant setting further includes a second time difference $\Delta 2$ being the time between stimulations in the right atrium and right ventricle.
- 20 10. Method according to claim 5, characterized in that the implant device setting is varied according to a predefined search pattern.
- 25 11. Method according to claim 1, characterized in that a measurement period is less than 30 seconds and preferably 10 seconds.
12. Method according to claim 1, characterized in that a measurement session list that may include calculated values from measurement periods obtained during a measurement session of less than 60 minutes and preferably less than 30 minutes.
- 30 13. A computer program product directly loadable into the internal memory storage of a processing means within a control unit, comprising the

software code means for performing the steps of any claims 1-12.

14. A computer program product that can be stored on a computer usable medium, comprising readable program for causing a processing means in a control unit to control an execution of the steps of any of the claims 1-12.

15. Pressure measurement device (2) including a pressure measurement guidewire (4) provided with a pressure sensor (6) adapted to perform pressure measurements in the left ventricle of a heart (8), the guidewire (4) is connected to a measurement unit (10) to receive pressure measurement values obtained from said sensor, and a processing means (12) for determining a real-time curve of the obtained pressure values and display means (14) for displaying said curve on said display means during a measurement period, characterized in that said processing means determines a real-time curve of first derivative values determined from the pressure curve and that said display means displays the determined first derivative curve, wherein said processing means also calculates and displays a value of a predefined parameter of the first derivative curve during said measurement period.

16. Pressure measurement device according to claim 15, characterized in that said predefined parameter is the average value of the maximum values of the first derivative curve.

17. Pressure measurement device according to claim 15, characterized in that said predefined parameter is the median value of the maximum values of the first derivative curve.

18. Pressure measurement device according to claim 15, characterized in that the pressure measurements are performed during a measurement period using predetermined medical implant settings in a medical implant (20) controlling the application of stimulation pulses at least in the left and right ventricles of the heart.

19. Pressure measurement device according to claim 16, 17 or 18

characterized in that said value of the predefined parameter is added to a measurement session list of measurement periods.

20. Pressure measurement device according to claim 18,
5 characterized in that each measurement period in the measurement session list have different medical implant settings.

21. Pressure measurement device according to claim 18,
characterized in that the pressure measurement is repeated for other
10 predefined implant device settings.

22. Pressure measurement device according to claim 18,
characterized in that an optimal implant device setting is identified as
the setting where the average value is maximal.
15

23. Pressure measurement device according to claim 18,
characterized in that the implant setting includes a first time difference
Δ1 being the time between stimulations in the left and right ventricles.

20 24. Pressure measurement device according to claim 23,
characterized in that the setting further includes a second time
difference Δ2 being the time between stimulations in the right atrium and right
ventricle.

25 25. Pressure measurement device according to claim 18,
characterized in that the implant device setting is varied during a
measurement session according to a predefined search pattern.

26. Pressure measurement device according to claim 15,
30 characterized in that values of the predefined parameter are displayed
in a three dimensional illustration.
